19. ABSTRACT (Continue on reverse if necessary and identify by block number) AFR 91-40, Industrial Water Treatment, 24 September 1984, initiated a new era in Air Force boiler water treatment. The study evaluates the current implementation status of this regulation through associated formal schools support, central laboratory use, check analysis performance, and AFESC Corrosion Analysis Reports. The evaluation identifies a lack of expertise at base level due to lagging technology transfer. The study then investigates the development of an "expert" computer program following AFR 91-40 and AFP 91-41, Industrial Water Treatment Procedures, 18 September 1987, to improve this information transfer and bolster management emphasis. Initial validation against Maxwell AFB central energy plant data identifies problem areas confirmed by plant personnel. Using program output, the author recommends a pretreatment system and generic chemicals that have an estimated effective annual savings of \$11,505. The study concludes that additional validation of the program is necessary and recommends a one-year test by graduates of AFIT's ENG 595, Industrial Water Treatment, course.

## PREFACE

---

This staff analysis project proposes a computer program to assist technology transfer to the civil engineering career field. The program, developed as part of this project, acts as an "expert" system in the water treatment of steam boilers. Experience has shown that poorly controlled boiler water treatment is detrimental to energy conservation, maintenance efficiency, and equipment life. Current boiler water treatment technology transfer began in 1977. Data from HQ AFESC/DEMM indicates less than full and effective implementation of boiler water treatment programs as presented in current directives. In September 1987, HQ AFESC/RDC expressed a need for further assistance in transitioning any new technology to civil engineering. This paper documents the development of the "expert" computer program and its evaluation as a technology transfer tool to improve boiler water treatment.

Copies of the software, including source code, may be obtained by writing HQ AFESC/DEMM, Tyndall AFB, Florida 34201-6001, or AFIT/DEE, Wright-Patterson AFB, Ohio 45433-5000. Requestors must supply a single 8-inch floppy disk. A copy of this staff analysis will be provided with the disk to explain the program. The software is compatible with WANG minicomputers purchased under the Air Force Buy Program for Civil Engineering and uses WANG BASIC with its system specific instructions and commands.

### ACKNOWLEDGMENTS

First and foremost, I give my greatest thanks to my wife, Marie, and our three children for their patience and understanding. They gave up much during the development of this project. Lt Col Robert L. Peters, my Air Command and Staff College project advisor, has my deep gratitude for providing the needed focus as well as encouragement. Appreciation goes also to SSgt William B. Wood, 3800 ABW/LGSF, and Mr. Herbert M. Lott, 3800 ABW/DEM DP, for their special and standard testing, respectively, of boiler water samples. Finally, a big thanks to the Maxwell AFB Civil Engineering Industrial Engineering Branch, 3800 ABW/DEI, for their computer support and assistance in understanding the intricacies of the WANG computer system.

---

## ABOUT THE AUTHOR

---

Major Michael J.W. Kaminskas graduated from Lehigh University in 1972, receiving a Bachelor of Science degree in Electrical Engineering. Commissioned in 1974 through ROTC while also doing graduate work at Lehigh, he entered active duty as a civil engineering officer at Carswell AFB, TX. There he learned the rudiments of cathodic protection of underground utilities and water tank interiors and took the Air Force Institute of Technology (AFIT) Corrosion Control Course. Selected in 1978 for the AFIT Education with Industry Program as a field chemist with the Illinois State Water Survey, Champaign, IL, he familiarized himself with the future Air Force water treatment technology. Next, a tour at HQ Air Force Engineering and Services Center, Tyndall AFB, FL, included a one-year assignment as the Chief, Corrosion Analysis Team. This traveling team analyzes the cathodic protection, water treatment, and protective coatings at bases world-wide. Selected for graduate work under the Senior Commanders' Education Program, he chose Rensselaer Polytechnic Institute, Troy, NY, and received a Master's of Engineering degree in Electric Power Engineering in 1982. His assignment to the AFIT School of Civil Engineering at Wright-Patterson AFB, OH, used his electrical and corrosion backgrounds. He ended his four-year tour there as Chief, Electrical Section and Assistant Professor of Electrical Engineering and Industrial Water Treatment. A remote tour as the Base Civil Engineer at Shemya AFB, AK, transitioned Major Kaminskas into his current assignment as member of the Air Command and Staff College (ACSC) class of 1988. Squadron Officers School in residence and ACSC by seminar round out his professional military education background.

**REPORT NUMBER** 88-1425

**AUTHOR(S)** MAJOR MICHAEL J. W. KAMINSKAS, USAF

**TITLE** "EXPERT" COMPUTER PROGRAM FOR BOILER WATER TREATMENT

I. Purpose: To investigate the development of an "expert" computer program that will improve technology transfer and bolster management emphasis in the area of boiler water treatment. The program follows the basic requirements of AFR 91-40, Industrial Water Treatment, and AFP 91-41, Industrial Water Treatment Procedures, as well as attempting to go beyond the calculations presented in AFP 91-41 in order to predict the final system operating point after all chemical addition.

II. Problem: Since the publication of AFR 91-40 in September 1984, there has been limited improvement in base-level boiler water treatment. Recurring areas of concern are the extent of expertise and management emphasis at base level. Often these result in acquiring expertise through the purchase of expensive proprietary chemicals and operating Air Force steam systems at less than optimum efficiency.

III. Data: Formal schools are the Air Force's primary means for technology transfer. However, at current rates it will take over five years to provide the minimum number of short course graduate

## CONTINUED

engineers and technicians needed. AFESC Corrosion Analysis Reports and AFIT on-site seminar trip reports since September 1984 confirm the limited implementation of AFR 91-40 and the extensive use of proprietary chemicals. A bright spot is the use of the central laboratory set up by AFESC to standardize chemical testing Air Force-wide. However, the check analysis program run by the laboratory indicates that overall testing accuracy is poor with over 50 percent of the results missing the target value by more than 30 percent. The computer program seeks to computerize the calculations for boiler water treatment in AFP 91-41, analyze equipment parameters for proper operation and print warnings if out of tolerance, predict the final boiler operating point after chemical addition, and use the operating point prediction to analyze the current treatment. The operating point prediction allows comparison of system and treatment changes, providing sufficient data output to perform an economic analysis.

Validation of the program against Maxwell AFB central energy plant data resulted in the confirmation of system operation problems already noted by plant personnel. Using the program to compare changes allowed the author to recommend a new pretreatment system that generates an estimated \$11,505 in effective annual savings. The base placed this recommended pretreatment system under design for construction in the near future. Unfortunately, the prediction of boiler chemical levels at the final operating point did not correlate with actual levels when the program was constrained to model actual operation.

IV. Conclusions: The computer program improves understanding of AFP 91-41 procedures and saves many hours of computation by hand calculator. Also, gathering data required for program input increases the interaction between plant, engineering, and management personnel. In its current form the program is not sufficiently "expert" to replace formal schools. For example, decision trees were large to analyze system problems, but the warnings produced were general in nature. To generate specific and detailed warnings will require very extensive decision trees. Thus, the current program still requires expertise to operate and evaluate output.

V. Recommendations: Using data from just one base is inadequate to fully validate this computer program. Limiting initial distribution of the program to major command industrial water treatment engineers and graduates of the AFIT industrial water treatment course places the program with those who have sufficient expertise. A one year application test with feedback to AFESC/DEMM and AFIT/DEE will expand the validation data base and allow AFESC to decide on future distribution.

## Chapter One

### INTRODUCTION

The Air Force Civil Engineering Corrosion Control Program administered by the Air Force Engineering and Services Center (AFESC) received a Functional Management Inspection by the Air Force Inspection and Safety Center in 1978. One finding of the inspection stated that guidance in the form of regulations, manuals, and pamphlets was out-of-date, in some cases not being changed in over 15 years, although updates were in various states of completion. Further, this was a contributing factor in the lack of base-level corrosion control program effectiveness. (11:--) Within the next six years every corrosion publication received a thorough review and underwent republishing. This project focuses on the industrial water treatment (IWT) component of corrosion control. It specifically looks at the current implementation of boiler water treatment directives and investigates a new technique to improve this implementation.

### WHY TREATMENT?

There are some 151 major and minor active duty Air Force installations around the world. These installations use steam from boilers to heat buildings and domestic hot water, cook food, clean clothing, humidify computers and hospital operating rooms, generate electricity, clean aircraft and vehicles, operate the gym's steam room, and even provide air conditioning. The steam systems require funds for construction, operation, and maintenance.

Air Staff figures from FY 86 Air Force real property records indicate a capital investment of \$606.6 million for large central heating plants over 750,000 British thermal units in size. Operation of these systems cost \$164.4 million in FY 86, with fuel going an additional \$128 million that same year. Maintenance in FY 86 ran another \$52.5 million. (21:--) When distribution piping, auxiliary equipment in outlying buildings, and smaller boilers are included, the author estimates a capital investment of at least double this figure, with an associated additional cost for operation, maintenance, and fuel.

"Industrial water is treated to prevent scale and corrosion, increase efficiency, prolong life, and reduce repair and

replacement of water-using equipment." (14:1) In 1979, AFESC estimated the corrosion losses due to inadequate water treatment for all industrial water systems (not just boilers) at \$180 million per year. (17:1) Thus, boiler water treatment has a significant effect in keeping our base utilities functioning in an efficient and cost effective manner.

The starting point for water treatment is the source of water, which may be a potable or nonpotable supply. The supply's water quality varies between every point on the globe, between seasons of the year, and between the sources of supply--well, river, lake, or any combination of these. In fact, the water quality may fluctuate minute to minute as two different sources are mixed to meet the demand. What makes a good potable water usually makes a poor boiler water. Therefore, boiler water treatment seeks an optimum water quality for boiler use.

The treatment requires a balance of several economic decisions. Specialized equipment or regulated chemical addition can be used separately or together to achieve effective boiler water treatment. Usually, mechanical means using specialized equipment backed up by chemical addition are more cost effective than using chemicals alone. The goal is to keep the boiler clean of scale and free of corrosion so as to ensure efficient heat transfer and long equipment life. Metering, chemical testing, and proper system operation are also an important part. When integrated with these areas, boiler treatment can result in maximum energy conservation, lengthened equipment life throughout the steam system, minimum water use, and the potential elimination of crisis maintenance. Without boiler water treatment you can expect waste of resources and abuse of the equipment.

The total integration of water treatment and testing into the complete system operation and vice versa is the final answer. In this way any malfunction of system equipment or operation can be detected by chemical testing with sufficient early warning to allow speedy repairs. Conversely, water treatment prevents system malfunctions from causing additional damage through corrosion or scale. Thus, the relationship between steam system operation and boiler water treatment is mutually beneficial.

#### CURRENT STATUS

Prior to AFR 91-40, Industrial Water Treatment, 24 September 1984, the Air Force had been using a boiler treatment program developed and supported by the US Bureau of Mines (BOM). The regulation changes affecting boiler water treatment included

1. new testing philosophy modeled after the successful program at the Illinois State Water Survey,

2. conversion of central laboratory support from the BOM to a commercial laboratory under contract to AFESC,
3. a revised quality control program modeled on the Environmental Protection Agency certified laboratory concept, and
4. the federal stock listing of all bulk chemicals needed for boiler water treatment.

While these changes may seem extensive, experienced base-level personnel would have little difficulty in transitioning. But, experience is in limited quantity at base level, and the initial method to gain experience is through education of engineers and training of technicians.

The AFIT School of Civil Engineering and Services (SOCES) received a draft of AFR 91-40 in January 1984 and incorporated it into the first course offering of ENG 595, Industrial Water Treatment, the next month. This course reached a total of 109 engineers and selected technicians, according to AFIT/DES figures, with two offerings each in FYs 84 and 85 and one offering each in FYs 87 and 88. Budget restrictions and priorities deleted the FY 86 offering. The graduates represent 59 installations world-wide. While AFIT SOCES can respond quickly to the career field's needs, only 36 percent of installations have taken advantage of ENG 595. Graduates that have been able to apply this education have very successful industrial water treatment programs. Wright-Patterson and Robins AFBs come first to the author's recollection. While AFIT SOCES focuses on managers and engineers during in-house courses, the school's on-site seminar experience repeatedly demonstrated that technology transfer had the greatest success when managers, engineers, and technicians received information commensurate with their needs. The training of technicians is equally important to the success of a program.

The Sheppard Technical Training Center, Sheppard AFB, TX, also received a draft of AFR 91-40 in early 1984. From FY 84 through the first half of FY 87, Course J3AZR54552 000, Boiler Water Treatment and Corrosion Control, offered technician training according to the old BOM procedures. In April 1987, Course J3AZR54552 001, Mechanical Systems Water Treatment, came on line and covers boiler water and cooling tower treatment per AFR 91-40. The two and one-half year time lag from publication of the new regulation to the first updated course offering can be attributed to many factors. First is the Air Training Command (ATC) procedure for making any changes to an established course, which includes ATC review of the changes. Secondly, as this course directly affects promotion testing, the appropriate career development courses and promotion tests had to be implemented simultaneously. Lastly, the design of ATC instruction material allows the most inexperienced instructor to meet all objectives.

These actions require much time to implement and this time lag directly affects the primary means of technology transfer to technicians.

HQ ATC figures from 1Lt Peter Cappello, Training Systems Programmer, DCS/Technical Training, show 363 technicians receiving training under the old course from FY 84 to FY 87. A training evaluation report covering November 1985 through November 1986 listed 68 percent of the 55 respondents rating the course marginal or unsatisfactory due to the outdated information presented in the course. (12:i) In FY 87, 68 technicians took the old course and the first updated offering trained 16 technicians from as many bases. The Trained Personnel Requirement for FY 87 was 155 (12:1), leaving 87 slots for the new course. Considering two personnel per base minimum (one boiler and one refrigeration technician), it will take another year and a half to transfer current IWT technology to each installation. Thus, minimum technology transfer occurs over five years after the publication of the regulation.

Fortunately, the current regulation and pamphlet are easy to read as the original authors specifically targeted the technicians. (22:--) With guidance, education, and training under way, AFESC has also standardized IWT world-wide through a central laboratory contract.

The central laboratory concept improved implementation of the new regulation by supplying standardized test kits and chemical reagents to perform the prescribed testing. The base personnel need only use a request form supplied by the laboratory to receive their order within two weeks world-wide. All costs are borne by the AFESC contract. This is most beneficial in getting capability to a base in a timely manner. For example, chemical reagents have a shelf life of six months to one year. While at Shemya AFB, the author identified a contractor at a radar facility using essentially the same testing procedures and chemicals as available from the central laboratory. However, many of their reagents were out-of-date since base supply maintained a double-order backup due to its remote location. Conversion to supply through the central laboratory will ensure chemical freshness and constant testing capability. Regardless of the obvious benefits, only 103 installations have taken advantage of this service since its inception in FY 85. Of these bases, 92 percent show consistent usage rates. The central laboratory also supports a check analysis program.

The check analysis program is the outgrowth of an AFIT master's degree thesis submitted in September 1983 by Capt Dennis C. Hughes. Capt Hughes challenged the effectiveness of the BOM check analysis program in which boiler samples were sent to the BOM laboratory for analysis by the same techniques as used at base level. Transportation time and lack of sample preservation

caused consistently inaccurate test results. Base-level management received little substance from this information. Capt Hughes recommended a program along Environmental Protection Agency lines. A preserved sample is sent to the installation, base personnel regularly engaged in testing then use standard IWT procedures to test the sample, and the results are mailed to the central laboratory. The laboratory compares the results to control tests taken on the same sample batch on the same day the base tested their sample. The laboratory sends the interpretation to the base, the major command, and AFESC. This is an excellent quality control measure that highlights poor testing techniques and deteriorated reagents. (9:14)

Nonparticipation in the check analysis program varied from 51 installations in FY 85 to 29 in FY 87, according to records provided by AFESC/DEMM. The central laboratory sent out 1108 boiler water samples for FY 85 through FY 87, requiring 8864 tests to be run (8 tests per sample). The installations accomplished 6464 tests for a 72.9 percent effort, with many samples receiving only partial testing. Testing accuracy showed only slight improvement over the last three years, except for conductivity and pH, which improved 40.8 and 12.9 percent respectively from FY 85 to FY 87 for test results within 20 percent of the target. A disturbing statistic concerns the percent of results not within 30 percent of the target value. For FY 87, overall 52.8 percent of the results missed even this liberal criteria. Results of individual tests with this percent in parentheses are as follows: lignosulfonate (81.05), sulfite (61.11), hydroxyl alkalinity (43.14), phosphate (40.85), methyl orange (M) alkalinity (33.01), phenolphthalein (P) alkalinity (27.13), conductivity (18.63), and pH (8.82). These figures include tests not run on sample results reported to the central laboratory. Thus, the lignosulfonate percent indicates few bases are using lignosulfonate as a sludge conditioner. The author interprets the sulfite percent as poor sample preservation and handling, allowing atmospheric oxygen to consume the sulfite in the sample. The remaining values are a mixture of sample preservation, testing technique, and reagent purity. Thus, these statistics indicate a need for increased base-level management. There are two indicators left to complete the understanding of current status--AFIT SOCES on-site seminar trip reports and AFESC Corrosion Analysis Reports.

Since the publication of AFR 91-40, AFIT instructors have consistently identified actions during on-site seminars that could produce yearly cost savings. A major problem was the continued use of commercial water treatment companies and their expensive proprietary chemicals. (16:--) Bases tend to use these commercial firms to overcome their lack of in-house expertise, since most companies provide "free" services when you purchase their chemicals. (19:--) These services are also a quick avenue for bases to get an IWT program on line. Policy and guidance

explicitly instruct bases to develop in-house programs using generic chemicals from federal stock lists. (17:--; 13:1; 14:1) Unfortunately, once a commercial firm establishes itself, inertia at the base makes it difficult to convert to an in-house program. Other problems include the practice of repair-by-replacement in lieu of preventive maintenance, to which IWT is a strong contributor. For example, during an on-site seminar in 1986, personnel from one Korean base related to the author that their base carried small packaged boilers as expendable bench stock items. These boilers did not receive any water treatment and had a life expectancy of one to two years. AFESC Corrosion Analysis Reports tell a similar story.

The Corrosion Analysis Team published 20 reports from September 1984 to March 1987. Eighteen of the reports listed steam systems as part of the infrastructure surveyed and 11 of these used proprietary chemicals with mixed results. Sixteen reports indicated problems with steam systems that boiler water treatment can impact. The recurrent theme in the reports is the less than full use of IWT capabilities available to maximize energy conservation, eliminate scale, and reduce corrosion to acceptable levels. Control of chemical levels was also inconsistent and testing ability paralleled the check analysis results mentioned earlier. These corrosion reports show that there is a wide range of expertise, capability, management emphasis, and effectiveness at base level. (10:--)

In summary, the status of boiler water treatment since publication of AFR 91-40 in 1984 can best be described as still transitioning towards the goal of an effective in-house program using generic chemicals. Formal technology transfer for engineers and technicians is slowly meeting each base's requirements. Use of the central laboratory supply is providing the standardization needed by technicians as they transfer between bases. The check analysis program indicates that bases require more management emphasis in testing accuracy. Finally, base-level personnel still use expensive proprietary chemicals and the services of commercial water treatment companies in their day-to-day boiler water treatment program. This last item has strong correlation to the level of technology transfer and expertise available at the installation.

#### THE PROBLEM

As explained above, base-level expertise in IWT and technology transfer directly affect a base's boiler water treatment program. In September 1987, HQ AFESC/RDC submitted a research topic to Air Command and Staff College requesting improved techniques for technology transfer. This further emphasizes the need for a vehicle other than formal schools to get technology to the working level, which includes the managers

overseeing the boiler water treatment program.

In the author's view, base-level management emphasis depends on three items. First, engineering and operational personnel need a mutually supporting level of expertise. Second, managers need quantitative information suitable to support economic analysis and produce a strong argument to commit funds. Third, the base needs an advocate to push the program. Note the common thread of expertise that interconnects these points. Technology transfer is, therefore, a key to management emphasis.

There are many factors observed by the author in addition to those already mentioned that contribute to a lack of boiler water treatment technology transfer.

1. The variation in water quality makes it difficult to simplify water treatment down to a few rules of thumb.
2. Water treatment is an operations function, with engineers usually getting involved only during construction projects or energy studies.
3. Managers view water treatment as either simple or complex and tend to expect the operational personnel to be fully knowledgeable.
4. Historical quantitative data dealing with treatment and steam systems is practically nonexistent. Current data tied to predictive calculations depends on the level of engineering expertise available to answer the "what if" question.
5. Many personnel, such as boiler operators, mechanics, steamfitters, and plumbers, influence boiler water treatment without fully understanding the effect of their actions.
6. Engineering and operational personnel have limited time to extensively study the subject or experiment with treatment. Anything that requires little time stands a greater chance for implementation or use.

The bottom line is economics. Increasing in-house expertise and developing a system-wide appreciation for the benefits of water treatment will only produce positive results. Following the Air Force guidance in boiler water treatment provides safe, efficient operation on the water side of our boilers at the lowest life cycle cost. The culmination of boiler water treatment expertise is accurate testing and interpretation of test results which detects problems and allows corrections to the steam systems before the base populace even notices.

To bridge this knowledge and experience gap, this staff analysis proposes an "expert" computer program to aid base-level technicians, engineers, and managers in their implementation and maintenance of a sound boiler water treatment program. The computer program will act as an "expert" system by performing tedious calculations and evaluating calculated results against actual data. The goal is to aid technology transfer and provide a useful tool for base personnel to evaluate options and performance. The initial quantitative data provided can form a basis for economic analysis, and the qualitative output can initiate management emphasis. Hopefully, it will also spur advocacy of boiler water treatment as the recognition of a problem and its significance are major milestones towards problem solution.

### RESEARCH GOALS

The publication of an updated AFR 91-40 occurred on 18 September 1987. The update was in two parts. A revised regulation by the same title and number contains the basic management requirements. The technical guidelines for implementation were split out into AFP 91-41, Industrial Water Treatment Procedures. The following tasks are set out for the "expert" computer program based upon the current publications:

1. Consolidate 23 pages of procedures found in AFP 91-41 for calculating boiler water treatment.
2. Determine the chemical treatment daily dosages beyond that provided by the initial dosage concept of the AFP 91-41 procedures.
3. Provide warnings whenever system test results indicate a problem in the operation of any mechanical component.
4. Compare actual daily chemical dosages for a given system operating condition to calculated dosages and interpret them to provide direction and management emphasis.
5. Provide a means for predictive analysis to gather data on the effects of system or chemical treatment changes. This data then becomes the basis for economic analysis to make comparative cost decisions.

Prior to delving into the computer program developed in this research effort, the next chapter attempts to reveal the basic concepts of the involved topics--"expert" computer systems and boiler water treatment.

## Chapter Two

### BACKGROUND

Certain concepts presented in this study may be new to the reader. This chapter seeks to provide sufficient clarification to meet the needs of those so interested.

#### "EXPERT" COMPUTER PROGRAMS

An intelligent computer program becomes an expert system when it "is capable of carrying out a task generally regarded as being difficult and requiring some degree of human expertise." (4:436) Knowledge is the key to the program, and it takes two forms: "common facts consisting of widely shared knowledge that is accepted by the professional and other accepted sources of data" and "heuristic...knowledge of good judgement and common good practice or 'rules of thumb' in a field." (5:26)

The intent of the proposed computer program is to bridge the gap between the contents of the current publications (14:--; 15:Ch1,Ch2,Ch4) and the daily operational problems that can affect a boiler and its associated systems. The "expert" computer program in the context of this project can best be described as rudimentary as it performs the calculations and analyzes for common problems, but it does not enter the realm of artificial intelligence where the program learns the state of knowledge/expertise of the engineer/technician and adjusts its presentation accordingly.

The contents of this computer program are based first upon the procedures set forth in AFP 91-41. (15:Ch2,Ch4,Ch6) Secondly, it uses "rules of thumb" gleaned from the author's research during course development for ENG 595, Industrial Water Treatment, at the AFIT School of Civil Engineering and Services. (2:--; 3:--; 7:--; 8:--) Discussions with water treatment experts in understanding the reasoning behind the current approach formed additional input. (22:--; 23:--; 24:--) Finally, sound system operation principles described in basic engineering texts complete the approach. (1:Ch1,Ch2,Ch34; 6:1-112) The most heuristic portion of the computer program consists of the estimated final system stability point--the final operating point after chemical addition which accounts for all boiler water treatment factors.

## BOILER WATER TREATMENT FACTORS

Simply put, boiler water treatment compensates for the detrimental effects that various water constituents have upon the operation and life expectancy of a steam system. The system can best be understood through the steam cycle. The cycle begins with the makeup water, usually provided from the potable water distribution system. The makeup receives pretreatment to convert it to a quality more suitable to the steam cycle. Pretreatment is an economic decision and consists mainly of some form of softening to remove hardness for scale control and alkalinity adjustment to control corrosion. The makeup enters a deaerating heater to preheat the water before it enters the boiler. The heater also boils the water to drive off oxygen and carbon dioxide which cause corrosion. The effluent of the deaerating heater is called feedwater as it feeds the boiler. The boiler produces steam which the steam distribution system distributes to the heat and energy transfer equipment. As the boiler produces pure steam, the water constituents from the makeup are left behind to concentrate in the boiler water. Controlled draining of the boiler, called blowdown, keeps the concentration of the boiler water within operational limits. As the steam traverses the distribution system and gives up energy in the utilization equipment it condenses back to the liquid phase. This condensate makes excellent boiler water as it has no pretreatment requirements. The condensate return system brings this water back to the deaerating heater where it mixes with the makeup to produce feedwater. The water has come full cycle, but the systems are not absolutely tight. Leakage occurs and increased makeup is the result.

Controlling leakage in the steam distribution and condensate return systems is very important. Loss of steam and condensate, termed outleakage, wastes energy and deprives the boiler of processed, good quality feedwater. Condensate is always preferred over makeup due to its quality, except when inleakage occurs. Due to pressure restrictions in utilization equipment, a leak in a steam coil may allow untreated potable water into the condensate return system. This inleakage is even more detrimental to system operation and efficiency than outleakage. The goal is to produce pure steam and return pure condensate back to the boiler so that makeup is kept to a minimum. Minimum makeup reduces pretreatment and blowdown. Under these conditions, the chemical dosages needed to counteract scale and corrosion in the boiler water are also kept to a minimum. While proper operation of the steam cycle is the main defense against scale and corrosion, chemical treatment and testing provide the second echelon of defense. Chemical testing monitors the treatment, as well as the system performance.

Each chemical added to a boiler has a specific purpose and a number of auxiliary effects, some positive and some negative.

Any treatment must be selected to provide a good engineering balance between effectiveness, ease of use, ease of testing, and cost. AFP 91-41 outlines a program which accomplishes this using treatments that have been proven over the past 15 to 20 years. In addition, the treatments include proper consideration for the means of water quality adjustment already mentioned and not just direct chemical addition to the boiler. The following discussion will look at the most prominent aspects of boiler water treatment beginning with controlling the detrimental effects of hardness salts.

Softening of the boiler makeup water using ion exchange resins is the principal means to control hardness salts of calcium and magnesium. These salts form heat insulating scale which destroys boiler tubes and robs system efficiency. Ion exchange softening is the primary pretreatment technique and the most economical way to remove hardness before it ever enters the boiler. Only chemicals can combat hardness once it gets into the boiler.

Phosphate-based chemicals are added to combine with the calcium hardness that enters the boiler. Calcium phosphate in the form of calcium hydroxyapatite is much easier to control than calcium sulfate or calcium carbonate. Magnesium phosphate is not one of the compounds desired, however, as it is difficult to control. With sufficient hydroxyl alkalinity in the boiler, the magnesium forms brucite (magnesium hydroxide) which then further combines with silica present to form serpentine. Calcium hydroxyapatite, serpentine, and brucite are the desirable precipitants. They have very low solubilities and form most of the total suspended solids found in a boiler.

The suspended solids make up the sludge in the boiler bottom. In heavy quantities, they settle out of the boiler water and bake onto the boiler tubes. This baked-on sludge is also very heat insulating. A sludge conditioner (sodium lignosulfonate) keeps these compounds in a fluid suspension. The fluidized sludge is then readily removed from the boiler during normal boiler blowdown. Blowdown not only controls the sludge produced in the boiler, but also controls the dissolved solids. As a bare minimum, a boiler must operate with sufficient blowdown to prevent scale formation and baked-on sludge. Blowdown alone can control scale and sludge, albeit very inefficiently. However, blowdown has limited capability in controlling corrosion.

Corrosion results first and foremost from the presence of oxygen. It causes extremely detrimental pitting of the boiler metal. Mechanical removal of oxygen by boiling the water in a deaerating heater is the most efficient method. The chemical addition of sulfite completes the removal process after the deaerator. Deaerating heaters usually are not found on small

boilers, which rely on sulfite alone for oxygen scavenging. Another form of corrosion results from the breakdown of alkalinity in the boiler.

Alkalinity comes in three forms: bicarbonate ( $\text{HCO}_3^-$  ion), carbonate ( $\text{CO}_3^{2-}$  ion), and hydroxyl ( $\text{OH}^-$  ion). The relationship between these alkalinity forms controls the water pH in the steam system. Bicarbonate and carbonate alkalinity contribute to scale and sludge, but also chemically break down in the boiler to form carbon dioxide. The carbon dioxide then forms carbonic acid in the condensate return system. However, sufficient alkalinity of the proper form (hydroxyl) maintains the boiler at the least corrosive pH for steel. Caustic soda is added to a boiler to provide the proper range of hydroxyl alkalinity. Thus, alkalinity must be adjusted to achieve the desired results. Excessive blowdown is one means to inefficiently control the negative alkalinity forms. Control by the pretreatment system is usually the most economical. Iron in the condensate indicates corrosion is occurring. An ammonia-like chemical, called an amine, will then be needed to prevent early failure of the condensate system. Alkalinity is but one of the forms of dissolved solids present in a boiler.

The water constituents dissolved in the boiler water concentrate as a boiler generates steam. The phrase "total dissolved solids" or TDS describes the level of this concentration. To keep the steam produced pure and further hinder scale formation, boilers are blown down to limit the TDS level or any other water constituent that imposes an operational limit. Operating a boiler within 10 percent of its TDS limit optimizes water usage and energy loss in the blowdown water. Since the test to accurately measure TDS takes one to two days to perform, the boiler water's conductivity (the ability to carry an electric current) is measured instead. As conductivity is the result of dissolved solids in the water, there is a measurable relationship between the conductivity and TDS. The conductivity test takes only a few minutes.

The testing associated with water treatment not only keeps the chemical additions on track, but also monitors the well being of the mechanical components. A malfunctioning softener manifests itself by hardness in its effluent. Detection of poor quality condensate allows identification of a leaking heat exchanger. Early detection of equipment problems is a beneficial by-product of boiler water treatment. In fact, proper system operation is 90 percent of corrosion and scale control. Chemicals handle the last 10 percent.

The above background into the chemical interactions of boiler water and the purpose of "expert" systems provides a foundation to comprehend the workings of the computer program presented in the next chapter.

## Chapter Three

### THE COMPUTER PROGRAM

The computer program, written in WANG BASIC, consists of four parts. The main program generates a data file and performs all file maintenance functions. It also assists the user in selecting all input data for each file record. The basic subroutine performs calculations per AFP 91-41 with a few variations to allow substitution of available data versus data specifically required by the pamphlet. It also analyzes system operation and informs the user of potential problems. The advanced subroutine goes beyond the AFP 91-41 calculations and attempts to predict the final operating point of the boiler, where chemicals dosed and water flows are in balance. This system model then allows further interpretation of actual test results versus those predicted, including the comparison of calculated and actual chemical dosages. The advanced subroutine also provides a rapid method to evaluate the effects of system changes. The data generated is sufficient to develop an economic analysis of the alternatives. Finally, the enthalpy subroutine selects the enthalpy value to calculate the maximum steam production possible for the boiler's operating pressure and altitude above mean sea level. Both the basic and advanced subroutines access the enthalpy subroutine in a manner having no user interaction. The enthalpy subroutine will not be discussed further in this staff analysis.

### DATA AND PROGRAM PHILOSOPHY

The program file names are "ESTMMAIN" for the main program, "ESTMAFF" for the basic AFP 91-41 calculations and system analysis, "ESTMSTST" for the advanced steady state calculations and treatment analysis, and "ESTMHG" for the enthalpy subroutine. The compiled programs use library "EIXXSRC," a standardized convention for engineering branch source code on the Civil Engineering Work Information Management System (WIMS). The object code for the main program resides in library "EIXXOBJ." The object code for the subroutines resides in library "EIXXSUBS." These are also WIMS standard conventions. These source and object codes reside in volume "PGM001." The data file "ESTM" resides in library "EIXXDATA" on volume "DAT001." The program uses IVAR data on the system to extract the user's computer ID (identification) and the volume where engineering

data resides, which is "DAT001" at Maxwell AFB. Proper storage by file, library, and volume is necessary to ensure proper linking of the main program with the subroutines. The author used called subroutines rather than one large program due to limitations in the compiler for the WANG BASIC computer language. It had difficulty compiling programs over about 2400 lines in length.

#### Data Records

The main program does a one-time creation of the data file and then performs all file maintenance. The records on the data file are uniquely described by a keyfield consisting of the user's computer ID, the date of record creation, a three character base ID abbreviation, a seven character building number for the boiler's location, a two character boiler designator, and a two character run indicator to describe the data in the record. A 45 character comment line allows expanded explanation of the data record's purpose, but it is not part of the keyfield. Also, at the start of the main program source code is a listing of all variables used throughout the four parts.

#### Data Input

The main program uses an asterisk in front of a test input to designate it as a test recommended by the pamphlet. The program also indicates the units of each input. Test inputs used in the calculations include steam quality in addition to makeup and condensate return quality. Boiler quality is used for comparison purposes only, as is the feedwater quality.

An added feature to increase comparison accuracy of the daily chemical dosage calculations to the actual dosages is the inclusion of a chemical purity input for each chemical used. While reagent grade chemicals used in chemical testing are nearly 100 percent pure, bulk water treatment chemicals are technical grade for economy and have purities ranging from 40 to 100 percent.

Tables in the main program allow selection of desired operational limits for total dissolved solids, phosphate, hydroxyl alkalinity, lignosulfonate, and sulfite levels. Suggested targets are also given with rationale. For ease of use, selecting any standard phosphate-based chemical is done simply by typing its associated number from a table. Neutralizing amine levels and dosages are not selected, but are automatically calculated to provide a 50/50 mixture of cyclohexylamine and morpholine. Other tables provided include percent of carbonate alkalinity breakdown in the boiler and the distribution ratio of the neutralizing amines. These tables attempt to improve understanding and increase accuracy of the advanced calculations.

Finally, the last function during the creation of the file record is the input of the chemical dosages on a pound per day basis. If the base uses nonstandard chemicals (chemicals not found in AFP 91-41), this section allows the inclusion of their alternate product names. Appendix 5 contains the sequence of screens presented to the user to provide the data described above to create a file record.

### Record Editing

The edit sequence for a file record can be followed in Appendix 6 and allows the user to review just the data in the record by selecting action number 1 in the screen shown at the bottom of page A6-3. In addition to this ability to review the record data, the user can review the selection criteria using the action numbers shown. Selection criteria action numbers directly access the associated specific subsections of the file record create sequence as described in Appendix 5.

The edit sequence has a unique feature in the multiple use of the screen shown at the top of pages A6-3 and page A6-9. Upon first appearance of this screen, the user can thumb through the data base by going to the next record, display the keyfield and comment line, select the file record for review and edit, or exit from the screen without taking any action. If the user enters a record for review or edit, upon the second appearance of this screen, the user must determine the handling of the record. Three options are available. First, by selecting action (R), the user can retain the existing record name (keyfield) with any changes that may have been made. Second, the edited record may be renamed by selecting action (C) and altering the keyfield displayed. This creates a new record, but also retains the old record with its unedited data and old name. Finally, by selecting action (E) the user exits from the screen without making changes to record data or keyfields. The remaining main program functions are one-time creation of the data file upon the first use of this program, the deletion of records following the instruction logic already provided, and the access of the call subroutines for calculations.

### Execution

As the user creates a data record, the program displays basic decision criteria and suggests inputs. It provides warnings about assumptions made to simplify AFP 91-41 and highlights or clarifies proper treatment philosophy. It also indicates where data can be found for program input. The requested input goes far beyond that needed to perform AFP 91-41 calculations, but the data should nevertheless be available on any major installation. Smaller installations may have to request limited support from the nearest main base or their supporting engineering function. The call subroutines allow selection of a data record and then

perform their calculations and analysis based on the data in that record. A decision for a hardcopy printout of the results is available at the end of the calculations. Both subroutines use the screen to scroll through the results prior to the printout decision. Once the calculations start, however, the user has no capability to stop the program, unless he has been given the "help" key by the computer system administrator.

A feature of this program not contained in AFP 91-41 is massflow analysis. A water constituent in a water flow should maintain its mass throughout the system, unless a specific treatment alters it or an undesirable condition is present. For example, the following calculations track calcium hardness through the steam cycle.

$$\begin{aligned} X_{mu} * Q_{mu} + X_{cr} * Q_{cr} &= X_f * Q_f \\ X_f * Q_f &= X_{bd} * Q_{bd} + X_s * Q_s \\ X_s * Q_s &= X_l * Q_l + X_{cr} * Q_{cr} \end{aligned}$$

Where, X = calcium hardness in ppm as CaCO<sub>3</sub>  
 Q = pounds of water per hour  
 mu = make up water after any pretreatment  
 cr = condensate returned to the boiler  
 f = feedwater  
 bd = blowdown  
 s = steam  
 l = losses, steam and condensate

A specific need for massflow analysis is the calculation of feedwater quantities. The author found that most boilers had some way of getting a makeup and a condensate return sample. Sampling feedwater, however, was difficult if not impossible. Thus, the feedwater inputs to the program are used for comparison only and do not participate in any further calculations. Note that AFP 91-41 bases all calculations on feedwater tests. The P alkalinity test is the only feedwater test used by the program, as P alkalinity does not follow massflow analysis through the deaerating heater.

Another feature not emphasized in AFP 91-41 is the variation of the quantity called "gallons" throughout the steam cycle. A gallon is a volume measurement that does not take into account the effects of pressure and temperature. AFP 91-41 assumes all feedwater weighs 8.33 pounds per gallon and uses this information to calculate the phosphate dosage. At normal potable water distribution conditions, a gallon of water weighs about 8.33 pounds. But, a gallon of water boiling at 150 pounds per square inch gauge weighs 7.353 pounds. A steam table can provide the specific volume (cubic feet per pound) of water under many conditions. (6:1-112) The user may select a more accurate pounds-per-gallon figure from the screen shown on page A5-13 or use the following equation.

Pounds/gallon = 0.1337 / specific volume

A clarification of other program aspects that expand upon AFP 91-41 is now in order.

The user indicates the processes available in the pretreatment system. However, due to the multitude of potential effects, it is left to the user to adjust the water qualities accordingly. This is not a problem if testing the effluent of the pretreatment system is possible. A problem arises when the intent is to predict the effect of system changes. The user should adjust makeup quality as a minimum; condensate quality may also need changing. Other predictive changes may require other adjustments.

From an operational standpoint, both calculation call subroutines take the rated steam capacity and, using altitude above mean sea level and feedwater temperature, calculate the maximum steam capacity possible for the boiler. The subroutines compare this result to the steam capacity being analyzed to ensure detrimental oversteaming is not occurring.

#### BASIC CALCULATIONS

The screens to access the basic calculations are the most straightforward. As mentioned previously, the calculation programs use the data from the selected record, provide an output on the screen for review, and provide a hardcopy of the results upon request. There are two ways to structure the data in a record for input to the basic calculations, one to optimize for AFP 91-41 calculations and one to optimize for analysis of system operation. The differences are striking.

To optimize the AFP 91-41 calculations, the user should start by locking a tested feedwater quality into the calculations. Only an operating system can provide this information. As the program is based upon the massflow calculations described earlier, making the makeup and condensate return quality values equal to the tested feedwater quality will fix the values of the feedwater quality in the calculations. Also, this will cause the program to warn of poor quality condensate and, possibly, of pretreatment problems. This is somewhat unrealistic because the feedwater quality will probably change for the operating conditions calculated by the program. Next, the user should set the steam and condensate losses to zero and make the steam quality pure, since AFP 91-41 assumes zero losses and pure steam. Finally, the oxygen content in the feedwater (the effluent of the deaerating heater) should be set to the minimum value of 0.007 ppm oxygen (as O<sub>2</sub>). AFP 91-41 assumes no oxygen in the feedwater.

Quite logically, to analyze system operation the data should reflect actual system operation. Specifically, the makeup, condensate return, and steam qualities should reflect actual tests or test averages over a given period. Also, since all systems leak to some extent, estimated water loss should not be zero. The user can determine an average water loss over a month by taking the difference between the average monthly makeup and blowdown as recorded on the AF Form 1459, Water Treatment Operating Log for Steam and Hot Water Boilers, or AF Form 1464, Monthly Steam Boiler Plant Operating Log.

The final point to be made concerning the basic calculations deals with the need for caustic soda addition. The only caustic soda dosage calculated is that needed for phosphate hydrolysis. Naturally occurring alkalinity is not taken into account in its ability to meet this need. Also, AFP 91-41 does not calculate the caustic soda needed for residual hydroxyl alkalinity or any other chemical reaction. Thus, the basic calculations for caustic soda may miss the real world requirements. The advanced calculations try to overcome the limitations in the basic calculations.

#### ADVANCED CALCULATIONS

The advanced calculations provide a better estimate of chemical dosages and expected test results to be found in the boiler. This call subroutine can then compare predicted tests and dosages to actual values. The basic and advanced calculations use total dissolved solids and silica to predict the final operating point for the boiler. In addition, the advanced calculations provide the following for total suspended solids: a makeup limit, an estimated test value limit, the cycles of concentration design limit, and the predicted actual cycles of concentration. Other modifications to the basic calculations provide increased accuracy.

Instead of using total hardness to calculate phosphate requirements, the advanced calculations use only calcium hardness. Magnesium hardness reacts with hydroxide and silica if available in sufficient quantity. This program provides warning if this is not the case. Magnesium phosphates are not desirable in a boiler, and the advanced calculations do not predict their formation. As for oxygen, the advanced calculations include determining the sulfite required to combine with any oxygen not removed by the deaerating heater. The effective operation of the deaerating heater is one system operation analysis included in the advanced calculations. There are two qualitative determinations provided in the advanced calculations, which do not increase accuracy but increase understanding of expected system final operating conditions.

Results of the naturally occurring hydroxyl alkalinity prediction in the boiler along with the neutralizing amine dosages can only suggest qualitative analysis. These constituents undergo so many complex interactions that precise estimates cannot be given. However, they do indicate the potential for gross problems in boiler operation. The program provides appropriate warnings. The accuracy of the predicted final operating point of a boiler rests with the iterative nature of the advanced calculations and the final interpretation of all information.

The main difference between the basic and advanced approaches is the multiple recalculation (iteration) of the chemical dosages and associated effects by the advanced program. The advanced program determines the resultant effects of the chemicals dosed and reaccomplishes the calculations after altering the makeup water quality accordingly. Thus, the quality of the makeup includes the effects of chemical treatment and becomes the principal variable in calculating makeup flow during each iteration. The program then chooses the largest makeup required between that needed for total dissolved solids or that needed for silica. Makeup, steam, and loss flows then calculate condensate return, feedwater, and blowdown. The cycles of concentration used for further calculations are equal to the feedwater flow divided by the blowdown flow. The program continues to perform iterations until the difference in the cycles of concentration between successive runs is within 0.0000001 cycle.

#### ANALYSIS AND INTERPRETATION

One convenience provided in the advanced calculations is the ability to constrain makeup flow to a given value. This greatly eases the comparison of predicted results with actual operation. Page A9-3 shows the sample screen, and Appendix 12 contains a sample hardcopy output. The main benefit from constraining the makeup is to fix the residual values of the chemicals dosed. Thus, any variation between predicted and actual dosages then stems from testing accuracy, which varies from correct values by over 30 percent about 50 percent of the time, inaccurate sampling techniques, defective system operation, or improper chemical feeding. Another point to remember is the overall nature of a steam system. Every flow is not consistent with every other flow at every moment. This means that averaging input values to this computer program over a month's time will be much more representative of overall system operation than using tests taken on one or two days.

Due to the many variables involved, including those not considered in this program, it is unwise to base a decision on a single calculation result. It is best to view the results as a composite whole that must interrelate. For example, the user

should compare the pressure and temperature on a deaerating heater, the design oxygen effluent of the heater, the daily sulfite dosage, the feeding method of the sulfite chemical, the chemical test procedures for sulfite, and any test procedures for measuring oxygen in the feedwater to determine if the sulfite dosage is in line and if the deaerating heater is operating properly. If the program prints out a warning, further investigation is necessary.

Thus, the first step recommended by the author to analyze an existing system is to use the basic calculations on actual system data, data not configured for the AFP 91-41 approach, to obtain an evaluation of the system operation. The next step is the use of constrained makeup in the advanced calculations to further understand the treatment and how the treatment interacts with the system operation. For example, adjusting the oxygen in the feedwater until the calculated sulfite dosage equals the actual dosage will provide a feedwater oxygen value that can be compared to an actual oxygen test. If predicted and actual oxygen values do not match, the user should look for reasons other than deaerator operation for the difference. Finally, results from using unconstrained makeup in the advanced calculations will indicate boiler operation under an AFP 91-41 treatment program. One caution--the makeup requirements, cycles of concentration, and design/actual operating levels for total dissolved solids, silica, and total suspended solids must always receive a review. If silica is the limit, then silica testing in the boiler water should begin. If the total suspended solids require the highest makeup or the lowest cycles of concentration, sludge may become a problem. In any case, the goal is energy conservation, efficient operation, and a clean bill of health during the annual boiler inspection.

One benefit of this program at every installation is the comparison of proprietary chemical treatments to AFP 91-41 treatment. As a minimum, this comparison of energy lost in blowdown, water use, and daily chemical dosages will provide the data needed in an economic evaluation.

A potential benefit is the base-level involvement of major command, AFIT, and AFESC industrial water treatment engineers through the use of this computer program. An installation having a problem with their treatment can provide the data requested in this computer program to form the basis of discussion with other experts. Most water treatment problems, in the author's experience, require broad data gathering to focus on the key elements and develop a solution.

A review of the hardcopy appendices and the next chapter will illustrate the analysis used by the author in the investigation of boiler number four at Maxwell AFB's Central Energy Plant.

## Chapter Four

### VALIDATION

Validation of any computer program ensures it works under all conditions and situations. However, the level of effort to validate this project can conservatively be estimated to exceed the time expended to develop and report on it. The following explains the strengths and weaknesses of this computer program during its application using Maxwell AFB plant data. The next chapter further clarifies these points in view of the research goals of this project. A plus for the output of this program is the implementation of the recommended changes in treatment. In this case, Maxwell AFB's civil engineering management is improving the pretreatment system and converting to AFP 91-41 based treatment.

#### MAXWELL AFB CENTRAL ENERGY PLANT DATA

Upon the advice of central plant personnel, the author selected boiler number four for analysis. This boiler, like the other four boilers in the same plant, operates at a pressure of 150 pounds per square inch gauge and has a rated capacity of 22,000 pounds of steam per hour. The author selected December 1987 for analysis due to winter operation and the ability to run additional tests for data not normally available. Current treatment consists of sodium sulfite fed to the deaerating heater, sodium hexametaphosphate and a proprietary sludge conditioner fed to the boiler, and a neutralizing amine (cyclohexylamine) fed to the steam header. Blowdown is continuous off the steam-water interface, and the bottom receives a blowdown two to three times a week. The boiler has a combustion efficiency of 76.2 percent and produced 45.7 percent of the total steam that month.

Results using actual system data in the basic calculations subroutine indicated excessive losses during the analysis month. A nonindustrial installation like Maxwell AFB should have losses between 1 and 5 percent of steam produced, whereas 15.67 percent loss occurred. The deaerating heater is not working properly and cannot achieve the design level of 0.04 ppm oxygen (as O<sub>2</sub>) in its effluent. Finally, plant personnel explained that due to direct contact steam cooking, morpholine could not be used. It has

been Air Force policy since the early 1970's to replace all direct contact steam cooking equipment with jacketed equipment. While the former equipment is cheaper, its purchase sentences the condensate return system to excessive corrosion because neutralizing amines cannot be used. Economics dictate replacing the steam equipment, rather than the condensate system.

Advanced calculations, with or without constrained makeup, repeatedly indicated a total suspended solids problem with the boiler. This is consistent with information from the last boiler inspection. The plant manager was investigating the use of increased blowdown, which would reduce this problem while further increasing the energy loss, water use, and chemical consumption.

These advanced calculations demonstrated no need to feed caustic soda to the boiler for hydroxyl alkalinity, although the basic calculations called for a daily dosage. Unfortunately, predicted levels of hydroxyl alkalinity were much too high compared to actual levels measured. Thus, further validation is necessary in this area with other water qualities. The proprietary sludge conditioner may have had an effect on the boiler pH and this prediction.

Constrained makeup calculations indicated about 0.485 ppm oxygen (as  $O_2$ ) in the feedwater, a tenfold increase over expected. As for other chemical levels, the dosages predicted rarely came within ten percent of the actual values. This can indicate testing accuracy problems or that the one time tests performed to get certain input values for the computer program diverged significantly from the average. Other possibilities include incorrect modeling of the primary chemical reactions expected in the boiler or unexpected reactions actually occurring. To evaluate these requires more analysis under varied conditions.

The predictive calculations indicated that reducing the steam and condensate losses would give the greatest improvement. This is as expected. These calculations also predicted the same problems of high total suspended solids and high hydroxyl alkalinity in the boiler. The former is due to using phosphate on unsoftened makeup water with a significant makeup water demand. The latter is due to the high levels of naturally occurring alkalinity in the makeup water. Split-stream softening of the central plant's makeup water eliminates these conditions.

The results of the computer-based analysis coupled with the author's experience provided the recommended treatment changes. However, while the program flagged the need and suggested solutions to investigate, the author's expertise selected the final approach. The recommended treatment changes below are not the output of the "expert" system, but do use the results of the program as input for the operation and economic analysis.

### RECOMMENDED TREATMENT CHANGES

Based on initial calculations, split-stream softening in the proportion of 71 percent of the flow through a hydrogen zeolite softener and 29 percent through a sodium zeolite softener will eliminate the total suspended solids and hydroxyl alkalinity problems in the boiler. Softening removes calcium and magnesium in the makeup, eliminating the high production of the large calcium hydroxyapatite molecule which is the main contributor to suspended solids. The hydrogen from the hydrogen zeolite converts alkalinity into carbon dioxide for removal in a degasifier column. The blended output of the two streams can produce a regulated amount of hydroxyl alkalinity in the boiler. This blending also eliminates the need for any caustic soda addition to the boiler. Nevertheless, this recommendation should conclude with an economic analysis to illustrate any benefits.

Four softeners, two each of each type to provide immediate backup and never allow hard water into the boilers, will cost approximately \$10,000 complete. They will handle the flow rates and softening capacity for the whole central energy plant, not just boiler number four. The softeners should have a life expectancy of 15 years. Replacement of the resins at the eight year point will cost another \$5,000. Regeneration chemicals to replenish the resins will add a yearly charge of \$155 for salt and \$3,215 for sulfuric acid. The effective annual cost of this additional effort is \$4,995 over the 15 years at a 10 percent interest rate. The basis for these figures is a total plant annual makeup requirement of 7 million gallons containing 40 ppm calcium hardness, 4 ppm magnesium hardness, and 200 ppm M alkalinity (all units as  $\text{CaCO}_3$ ).

The energy savings for the reduction in blowdown due to the new softeners and repair of the deaerating heater comes to about \$5,095 per year. Water savings add another \$400 per year. Chemical savings per year due to the recommended pretreatment and reduced blowdown come to \$1,725 for phosphate, \$400 for sulfite, \$1,015 for neutralizing amine, and \$7,865 for sludge conditioner. The sludge conditioner savings stem mainly from conversion from the proprietary chemical now being used to the sodium lignosulfonate listed in AFP 91-41. To compensate for the addition of morpholine to the cyclohexylamine already used, the neutralizing amine savings listed is half that estimated. Morpholine use is contingent upon elimination of direct contact steam cooking. These annual savings come to \$16,500. Thus, the effective annual savings of the new pretreatment is \$11,505. The payback of ten months on first year investment is an attractive return. Reducing steam and condensate losses below five percent will more than triple these savings. The above figures are conservative and illustrate typical improvement for medium-sized central plants, especially when converting from proprietary chemicals to AFP 91-41 generic chemicals.

## Chapter Five

### FINDINGS

The "expert" computer program can improve the technology transfer of boiler water treatment by aiding the analysis and interpretation of treatment alternatives. However, to get to the point where it rivals formal schools will require many more lines of computer code than currently written. The problem rests with the many variations in possible chemical and system interactions, resulting in large decision trees to select a response to a single parameter. Therefore, at this time, the computer program is more applicable for use by formal school graduates than for general use by base personnel.

One area demonstrated during the development of this program to require some expertise is the adjustment of record data to model alternate courses of action. This requires an experience level far above that which can be programmed into the "expert" system at this time. In particular, the user needs a grasp of the capabilities and output quality of pretreatment systems and their overall effect upon the system using the makeup water quality in question.

The continued validation of this computer program should center on the advanced calculations and their determination of chemical dosages, interpretation of these against actual dosages, and the resulting benefit of predictive analysis. There was excessive difference between calculated and actual dosages for each chemical used at Maxwell AFB under the constrained makeup advanced calculation mode. These differences can be due to problems in sampling, testing, chemical feeding, or the basic assumptions behind the calculations themselves. The author primarily suspects the testing and assumptions. Testing accuracy is one possibility, but a more likely one is the use of single test results in the data record for some inputs while others were monthly averages. The single test may have been taken at a moment when the values tested were not representative of the average situation throughout the month. As for the assumptions in the calculations, one water quality and one boiler are insufficient to declare success or failure. The calculations must be run against other systems at other locations to clarify their deficiencies and validate their accuracy.

## CONCLUSIONS

The consolidation of AFP 91-41 procedures in the computer program and the step-by-step process to create a data record does improve understanding and saves many hours of computation by hand calculator. One interesting response from the Maxwell AFB plant personnel occurred when they learned that the boiler's altitude above mean sea level affects its maximum steam production. Being ex-Navy shipboard boilermen like many other Air Force civilian plant personnel, they never had to consider altitude. This one point of technology transfer should increase the awareness of the potential to oversteam and damage a boiler.

Another positive action during program development was the interaction between plant, engineering, and management personnel. The data collection required promotes this interaction as does the interpretation of warnings identified by the calculation subroutines. This initial dialogue can become the basis for consistent management review and emphasis.

Computer warnings concerning mechanical system operation were effective in identifying problems at the Maxwell AFB central energy plant. However, to limit the variables involved, the decision trees concentrated upon hardness, total suspended solids, and alkalinity leakage from the more common pretreatment systems; the pressure and temperature of deaerating equipment; the quality of returned condensate; and the amount of steam and condensate losses. As warnings get more specific, the decision trees must test the interrelationship between and among more variables. Even then there is probably more than one reason for the warning to occur. Thus, rather than identify every possible situation, the warnings were made general enough to flag a problem and provide areas for further investigation.

## RECOMMENDATIONS

Distribution of the computer program should be limited initially to major command industrial water treatment engineers and graduates of the AFIT course, ENG 595, Industrial Water Treatment. A one year application test with feedback to AFESC/DEMM and AFIT/DEE will expand the validation data base. This is particularly necessary to ensure that instructions and warnings in the program cover the full range of water quality. It will also identify the prediction accuracy of the basic chemical reactions coded into the program. After the year long test, AFESC can decide to distribute this report and associated computer program on floppy disk to each installation or to limit it to graduates of formal industrial water treatment courses.

## Appendix One

### MAIN PROGRAM FOR DATA RECORD MANAGEMENT AND INPUT SELECTION

```
000010 * THIS PROGRAM CALCULATES THE MASS FLOW QUANTITIES AND CHEMICAL
000012 *   DOSAGES FOR STEAM BOILER WATER TREATMENT USING RATED BOILER
000014 *   QUANTITIES ADJUSTED FOR ACTUAL OPERATING CONDITIONS, QUALITY
000016 *   OF AVAILABLE MAKEUP, AND QUALITY OF CONDENSATE RETURNED
000018 *   ACCORDING TO AFP 91-41, INDUSTRIAL WATER TREATMENT PROCEDURES,
000020 *   (18 SEPTEMBER 1987) AND BEYOND.
000022 *
000024 * THE MAIN PROGRAM CREATES AND MAINTAINS DATA RECORDS ON THE FILE.
000026 *   THE CALCP SUBROUTINE ANALYZES SYSTEM OPERATION AND CALCULATES
000028 *   CHEMICAL DOSAGES ACCORDING TO AFP 91-41.
000030 *   THE CALCS SUBROUTINE CALCULATES CHEMICAL DOSAGES AT THE
000032 *   ESTIMATED FINAL SYSTEM OPERATING POINT, TAKING INTO ACCOUNT
000034 *   THE MAJOR CHEMICAL REACTIONS AND THEIR EFFECTS, AND ANALYZES
000036 *   THE TREATMENT ACTUALLY BEING PROVIDED TO THE BOILER.
000038 *
000040 *****      DESCRIPTION OF VARIABLES
000042 *
000044 *      VARIABLE      DESCRIPTION
000046 *
000048 *      XXXX(N)      AN ITERATED VARIABLE USED IN ADVANCED
000050 *                   CALCULATION SUBROUTINE
000052 *                   XXXXX DENOTES ANY CHARACTER STRING
000054 *      AMSL      ALTITUDE OF BOILER ABOVE MEAN SEA LEVEL
000056 *      BASE$      INSTALLATION WHERE BOILER IS LOCATED
000058 *      BASEID$    BASE ID 3 LETTER ABBREVIATION
000060 *      BICARBF    BICARBONATE ALKALINITY IN FEEDWATER
000062 *      BLDG$      BUILDING NUMBER WHERE BOILER IS LOCATED
000064 *      BLRSI      OPERATING LEVEL OF SILICA IN BOILER
000066 *      BLRTDS     OPERATING LEVEL OF TDS IN BOILER
000068 *      BLRTSS     OPERATING LEVEL OF SUSPENDED SOLIDS IN BOILER
000070 *      BLR$       BOILER DESIGNATION (NUMBER, LETTER, BOTH, OR ?)
000072 *      CACR       CALCIUM HARDNESS IN CONDENSATE RETURN
000074 *      CAF        CALCIUM HARDNESS IN FEEDWATER BY CALCULATION
000076 *      CAFT       CALCIUM HARDNESS IN FEEDWATER BY TEST
000078 *      CAMU       CALCIUM HARDNESS IN MAKEUP
000080 *      CARBF      CARBONATE ALKALINITY IN FEEDWATER
000082 *      CARBPC     % CARBONATE ALKALINITY BREAKDOWN IN BOILER
000084 *      CDOF      CARBON DIOXIDE IN FEEDWATER
```

000086 *	CHADR	DISTRIBUTION RATIO FOR CYCLOHEXYLAMINE
000088 *	CHAF	CYCLOHEXYLAMINE PPM REQUIRED IN FEEDWATER
000090 *	CHAPC	PER CENT CYCLOHEXYLAMINE IN CHEMICAL USED
000092 *	CHAPCBD	PER CENT CYCLOHEXYLAMINE IN BLOWDOWN
000094 *	CHAW	WEIGHT OF CYCLOHEXYLAMINE DOSAGE PER DAY
000096 *	CHEMCGC(N)	CYCLES OF CONCENTRATION CONSIDERING CHEMICALS
000098 *		DOSED TO BOILER (ITERATION)
000100 *	COMMENT\$	COMMENT EXPLAINING THE NATURE OF THE DATA
000102 *		RECORD - USE AS SEE FIT
000104 *	CUCR	COPPER IN CONDENSATE RETURN
000106 *	CYC	CYCLES OF CONCENTRATION
000108 *	CYCSIA	ACTUAL CYCLES BASED ON SILICA
000110 *	CYCSID	CYCLES BASED ON SILICA - DESIGN LIMIT
000112 *	CYCTDSA	ACTUAL CYCLES BASED ON TDS
000114 *	CYCTDSD	CYCLES BASED ON TDS - DESIGN LIMIT
000116 *	CYCTSSA	ACTUAL CYCLES BASED ON TSS
000118 *	CYCTSSD	CYCLES BASED ON TSS - DESIGN LIMIT
000120 *	DATE\$	DATE (YYMMDD)
000122 *	DEEDATAVOL\$	VARIABLE NAMING VOLUME WHERE ENGINEERING DATA
000124 *		IS STORED BY WIMS CONVENTION
000126 *	DENSF	DENSITY OF FEEDWATER IN POUNDS/GALLON
000128 *	DMGF	DELTA VARIABLE FOR MAGNESIUM IN FEEDWATER TO

## CALL SUBROUTINE FOR ADVANCED CALCULATIONS AND TREATMENT ANALYSIS

```

000010 SUB "CALCS"
000012 * THIS SUBPROGRAM CALCULATES THE MASSFLOW QUANTITIES AND CHEMICAL
000014 *   DOSAGES FOR STEAM BOILER WATER TREATMENT USING RATED BOILER
000016 *   QUANTITIES ADJUSTED FOR ACTUAL OPERATING CONDITIONS, QUALITY
000018 *   OF AVAILABLE MAKEUP, AND QUALITY OF CONDENSATE RETURNED.
000020 *
000022 *   THIS PROGRAM GOES BEYOND AFP 91-41, INDUSTRIAL WATER TREATMENT
000024 *   PROCEDURES, (18 SEPTEMBER 1987) AND ESTIMATES THE FINAL
000026 *   OPERATING POINT OF THE BOILER TAKING INTO ACCOUNT ALL CHEMICAL
000028 *   EFFECTS AND COMPARES RESULTS TO ACTUAL OPERATIONAL TESTING AND
000030 *   CHEMICAL DOSAGES.
000032 *
000034 * THE MAIN PROGRAM CREATES AND MAINTAINS THE DATA FILE THAT THIS
000036 *   SUBPROGRAM ACCESSES
000038 *
000040 * A DESCRIPTION OF VARIABLES IS AVAILABLE AT THE BEGINNING OF THE
000042 *   THE MAIN PROGRAM
000044 *
000046 ***   INITIALIZE VARIABLES TO ZERO AND SET GENERAL INFO
000048 * THE WANG VS 100 COMPUTER AUTOMATICALLY INITIALIZES ALL
000050 *   VARIABLES TO ZERO

\*\*\*\*\*  
\* WARNING \*  
\* DO NOT USE COMMAS \*  
\* IN NUMERICAL INPUTS \*  
\*\*\*\*\*

NOTE - CONDUCTIVITY IS NOT AN INPUT ANYWHERE IN THIS PROGRAM. THE RELATIONSHIP BETWEEN CONDUCTIVITY AND TOTAL DISSOLVED SOLIDS IS NOT A FIXED RATIO. AFP 91-41 DOES USE AN APPROXIMATION HOWEVER. HIGHLY RECOMMEND SAMPLES BE TESTED FOR CONDUCTIVITY, TOTAL DISSOLVED SOLIDS, AND TOTAL SUSPENDED SOLIDS TWICE A YEAR. THE BASE FUELS LAB CAN PERFORM THE LATTER TWO TESTS. THEN DETERMINE THE TOTAL DISSOLVED SOLIDS/CONDUCTIVITY RATIO FOR EACH SAMPLE. ONCE THE RATIO IS FOUND THE BOILER CAN BE OPERATED ON A CONDUCTIVITY LIMIT THAT RELATES TO THE TOTAL DISSOLVED SOLIDS LIMIT WITH GREAT CONFIDENCE. THE SAMPLE USED MUST BE AS CLOSE AS POSSIBLE TO THE FINAL OPERATING POINT. ADJUST TREATMENT AND RERUN THESE TESTS UNTIL THE DESIRED OPERATING POINT IS REACHED.

PRESS <ENTER> TO CONTINUE

\*\*\*\*\*

# STEAM BOILER WATER TREATMENT PROGRAM

OTHER SOURCES OF THE DATA NEEDED FOR THIS PROGRAM ARE AS FOLLOWS:

MAKEUP WATER QUALITY - AF FORM 2752, ENVIRONMENTAL SAMPLING DATA  
HOSPITAL BIOENVIRONMENTAL ENGINEER  
CE ENVIRONMENTAL SUPPORT SHOP (WATER + WASTE)  
LOCAL WATER UTILITY - DIFFERENT FORM  
AFESC CORROSION ANALYSIS REPORT - DIFFERENT FORM  
SYSTEM OPERATION - AF FORM 1464, MONTHLY STEAM BOILER PLANT OPERATING LOG  
HEAT SHOP OR CENTRAL HEATING PLANT AS APPROPRIATE  
BOILER WATER TESTS - AF FORM 1459, WATER TREATMENT OPERATING LOG FOR STEAM AND  
HOT WATER BOILERS  
HEAT SHOP OR CENTRAL HEATING PLANT AS APPROPRIATE

THE BASE FUELS LAB IS THE ONLY FUNCTION ON BASE THAT CAN READILY PERFORM THE  
THE TOTAL DISSOLVED SOLIDS AND TOTAL SUSPENDED SOLIDS TESTS!

ALL OTHER TESTS CAN BE PERFORMED WITH EQUIPMENT AND REAGENTS AVAILABLE UNDER  
THE AFESC CENTRAL LABORATORY CONTRACT. THESE ITEMS ARE FREE TO ANY BASE UPON  
REQUEST.

PRESS <ENTER> TO CONTINUE

# STEAM BOILER WATER TREATMENT PROGRAM

FOR ACCURATE TESTING, ACCURATE SAMPLING MUST BE DONE!

THE FOLLOWING RULES WILL ENSURE A GOOD START.

1. REVIEW PARA. 6-6, METHODS OF SAMPLING, IN AFP 91-41.
2. ALWAYS USE A SAMPLE COOLER WHENEVER THE SOURCE IS AT PRESSURE AND OVER 100 DEGREES FAHRENHEIT.
3. FILL SAMPLING CONTAINER ABOUT 1/8TH FULL OR LESS AND CAP. AGITATE WELL AND DRAIN. REPEAT TWO TIMES TO FULLY PREPARE THE CONTAINER.
4. DO NOT USE A SAMPLING CONTAINER CONTAMINATED OR CONTAINING ANY ITEM TO BE TESTED. THAT IS, NO GLASS IF SILICA IS BEING TESTED OR COPPER IF COPPER IS OF INTEREST. FOR MOST TESTING PLASTIC IS BEST.
5. RUN THE SAMPLE WATER LONG ENOUGH TO FLUSH THE SAMPLING LINE AND COOLER AND GET A REPRESENTATIVE SAMPLE FROM THE SOURCE.
6. EXTEND THE SAMPLE LINE TO THE BOTTOM OF THE SAMPLE CONTAINER USING PLASTIC TUBING, PREFERABLY TYGON. RUN THE SAMPLE TO OVERFLOW THE SAMPLE CONTAINER AT LEAST TWO CONTAINER VOLUMES AND CAP.

PRESS <ENTER> TO CONTINUE

\*\*\*\*\*

INSERT INFO IN SPACES SHOWN, PRESS <ENTER> WHEN DONE

## \*\* STEAM PRODUCTION DATA \*\*

\*\*\* THIS PROGRAM IS DESIGNED FOR USE WITH A \*\*\*  
SINGLE BOILER. IF ANALYZING A MULTIBOILER PLANT,  
PROPORTION THE TOTAL PLANT MASSFLOW TO JUST ONE  
BOILER. THUS, ANALYZE EACH BOILER SEPARATELY.

\*\*\*

OPERATING GAUGE PRESSURE OF BOILER = \*\*\*0.00

RATED STEAM PRODUCTION (POUNDS/HOUR) OF BOILER = \*\*\*\*\*0.00

ACTUAL STEAM PRODUCTION INVESTIGATED (POUNDS/HOUR QS) = 1.00

ESTIMATED LOSSES STEAM AND CONDENSATE (POUNDS/HOUR QL) = \*\*\*\*\*0.00

NOTE THAT GOOD PRACTICE IS TO KEEP QL AS SMALL AS POSSIBLE BASED UPON STEAM USE!  
ALSO NOTE - AFP 91-41 ASSUMES NO LOSSES IN ITS CALCULATIONS!

STEAM BOILER WATER TREATMENT PROGRAM

MASSFLOW CALCULATIONS INDICATE THAT MOST WATER  
CONSTITUENTS WILL MIX WELL WHEN THE MAKEUP AND  
CONDENSATE FLOWS CONVERGE IN THE DEAERATING HEATER.

THUS, MOST CONSTITUENT LEVELS CAN BE CALCULATED IN  
FEEDWATER USING MAKEUP AND CONDENSATE VALUES.

USING P ALKALINITY TO COMPUTE FEEDWATER LEVELS IS  
TOO COMPLEX TO DO BY SIMPLE CALCULATION BASED UPON  
MASSFLOW. THE PH, CO2, ALKALINITY RELATIONSHIP  
CHANGES AS THE FEEDWATER GOES THROUGH THE DEAERATING  
HEATER.

NOTE HOWEVER THAT THE M ALKALINITY RELATIONSHIP TO  
MASSFLOW DOES SEEM TO HOLD.

STEAM BOILER WATER TREATMENT PROGRAM

INSERT INFO IN SPACES SHOWN, PRESS <ENTER> WHEN DONE

\*\* STEAM QUALITY OF INTEREST \*\*

TOTAL DISSOLVED SOLIDS IN STEAM (ASSUME 0 IF PURE) = \*\*\*0.00

SILICA IN STEAM (ASSUME 0 IF PURE) = \*\*\*0.00

RECOMMEND MEASUREMENT OF STEAM PURITY TWICE A YEAR.  
TAKE STEAM SAMPLE AT FIRST HIGH PRESSURE DRIP COMING  
OFF BOILER. THERE ARE MANY REASONS FOR STEAM NOT TO  
BE PURE. ACCEPTED GOOD PRACTICE IS TO HAVE PURE  
STEAM. IF TESTING INDICATES POOR STEAM QUALITY,  
CHECK STEAM SEPARATORS, BOILER WATER LEVEL, OIL IN  
FEEDWATER, OVERSTEAMING, AND TOTAL DISSOLVED SOLIDS  
LEVEL IN BOILER. IF ALL EQUIPMENT AND OPERATION IS  
PROPER WITHOUT OIL CONTAMINATION OR OTHER REASON FOR  
FOAMING, REDUCE TOTAL DISSOLVED SOLIDS LEVEL UNTIL  
STEAM BECOMES PURE. THIS LAST STATEMENT HOLDS TRUE  
FOR SILICA ALSO.

ABOVE DATA CORRECT ( Y OR N ) OR (E)XIT ?

# STEAM BOILER WATER TREATMENT PROGRAM

NOTE - THE PHOSPHATE DOSAGE APPLIES TO CALCIUM HARDNESS, NOT TOTAL HARDNESS, OF THE FEEDWATER. MAGNESIUM'S PREFERENTIAL REACTION IS WITH HYDROXIDE, THEN SILICA, AND FINALLY PHOSPHATE. MAGNESIUM SILICATE (SERPENTINE) IS MUCH MORE DESIRABLE THAN MAGNESIUM PHOSPHATE IN THE SAME WAY THAT CALCIUM PHOSPHATE (HYDROXYAPATITE) IS PREFERRED OVER CALCIUM SULFATE. IN EACH CASE, THE PREFERRED COMPOUND IS EASILY HANDLED WITH THE STANDARD SLUDGE CONDITIONER.

NOTE - AFP 91-41 ASSUMES 8.33 LBS/GALLON OF WATER TO DETERMINE THE GALLONS OF FEEDWATER AND CALCULATE THE PHOSPHATE NEEDED TO REACT WITH HARDNESS. PRESSURE AND TEMPERATURE AFFECT THIS VALUE AND THIS AFFECTS THE ACTUAL GALLONS THAT WILL BE MEASURED BY A WATER METER. THIS IS WHY CALCULATIONS ARE DONE IN POUNDS/HOUR AS IT IS NOT VOLUME DEPENDENT!

INSERT INFO IN SPACES SHOWN, PRESS <ENTER> WHEN DONE

NEUTRALIZING AMINE DOSAGES ARE DIFFICULT TO CALCULATE DUE TO MANY VARIABLES.  
FEEDWATER ALKALINITY IS IMPORTANT TO THE DETERMINATION OF AMINE DOSAGES.

AFP 91-41 SEEKS A 50/50 MIXTURE OF CYCLOHEXYLAMINE AND MORPHOLINE INITIALLY.  
GOAL IS TO ACHIEVE FINAL OPERATION AT PH 7.5 TO 8.0 THROUGHOUT THE  
CONDENSATE SYSTEM.

USE FREQUENT TESTS AND ADJUSTMENTS INITIALLY.  
THEN TEST THE CONDENSATE SYSTEM THOROUGHLY TWICE YEARLY THEREAFTER.

PURITY (%) OF CYCLOHEXYLAMINE USED (60 OR 98) = 1.00  
PURITY (%) OF MORPHOLINE USED (40, 91, OR 99) = 1.00

ABOVE DATA CORRECT ( Y OR N ) OR (E)XIT ?

STEAM BOILER WATER TREATMENT PROGRAM

INSERT INFO IN SPACES SHOWN, PRESS <ENTER> WHEN DONE

DISTRIBUTION RATIO IS A MEASURE OF THE RELATIONSHIP BETWEEN THE AMINE IN  
VAPOR PHASE AND THE AMINE IN LIQUID PHASE. THE HIGHER THE RATIO THE MORE  
EASILY THE AMINE EVAPORATES AND STAYS IN VAPOR PHASE.

BOILER PRESSURE PSIG	DISTRIBUTION RATIO	
	CYCLOHEXYLAMINE	MORPHOLINE
0	4.0	0.40
150	9.0	0.85
450	9.4	1.33
600	8.2	1.02

SELECTED DISTRIBUTION RATIO FOR CYCLOHEXYLAMINE = 4.00  
SELECTED DISTRIBUTION RATIO FOR MORPHOLINE = 0.40

NOTE THE MIXTURE RATIOS AND MAXIMUM DOSAGES ALLOWED FOR NEUTRALIZING AMINES  
PER AFP 91-41.

DO NOT USE AMINES IF STEAM COMES INTO DIRECT CONTACT WITH FOOD. IMMEDIATELY  
HAVE SERVICES PROGRAM EQUIPMENT REPLACEMENT AS THIS IS AGAINST STATED POLICY.

ACTUAL DOSAGE OF CYCLOHEXYLAMINE (LB/DAY)= 5.71  
ACTUAL DOSAGE OF MORPHOLINE (LB/DAY)= 0.00

\*\*\*\*\* BOILER QUALITY OF INTEREST \*\*\*\*\*  
\*\*\*\*\* FROM WATER TREATMENT LOG (AF FORM 1459) \*\*\*\*\*

HYDROXYL ALKALINITY	(PPM CaCO3)	286.20
TOTAL DISSOLVED SOLIDS	(PPM)	1,524.70
PHOSPHATE	(PPM PO4)	48.30
SULFITE	(PPM SO3)	49.50
LIGNOSULFONATE	(PPM TANNIC ACID)	0.00
PH		11.29

TEMPER COMMENTS BELOW IF ALTERNATE CHEMICALS ARE USED VICE AFP 91-41 STOCKS.

WARNING-CALCULATIONS PREDICT EXCESSIVE SUSPENDED SOLIDS IN BOILER.  
INVESTIGATE HARD MAKEUP WITH NO PHOSPHATE, SOFTENING AND PHOSPHATE, AND  
ELIMINATION OF CONDENSATE RETURN HARDNESS CONTAMINATION!

HYDROXYL ALKALINITY OR BOILER PH IS LOW - EXPECT CORROSION AND BAD REACTIONS!

LIGNOSULFONATE OPERATING LEVEL IS LOW - MAY RESULT IN BAKED-ON SLUDGE!

WARNING-CALCULATED BOILER M ALKALINITY EXCEEDS 20% OF BOILER TDS. THIS CAUSES  
DETRIMENTAL FOAMING. SPLIT-STREAM SOFTEN, DEALKALIZE, OR USE SODIUM BISULFITE  
TO REDUCE ALKALINITY.

\*\*\* SUMMARY OF ACTUAL AND CALCULATED CHEMICAL DOSAGES \*\*\*

ANALYSIS NOTE - IF PURPOSE IS TO MODEL ACTUAL SYSTEM OPERATION, THEN DATA RECORD SHOULD REFLECT THE OPERATIONAL LIMITS BEING USED FOR EACH CHEMICAL OR TEST AND THE MAKEUP SHOULD BE CONSTRAINED TO THE ACTUAL METERED MAKEUP VALUE. THIS SHOULD RESULT IN BLOWDOWN EQUIVALENCE BETWEEN ACTUAL SYSTEM AND CALCULATED RESULTS. THEN COMPARISON OF ACTUAL AND CALCULATED DOSAGES IS OF VALUE. FOR EXAMPLE - ACTUAL SULFITE DOSAGE GREATER THAN CALCULATED COULD INDICATE MORE OXYGEN IN THE FEEDWATER THAN ESTIMATED, AN OUT OF CALIBRATION PRESSURE OR TEMPERATURE GAUGE ON THE DEAERATING HEATER, OR A DEFECTIVE DEAERATING HEATER. SIMILARLY, A HIGH PHOSPHATE DOSAGE CAN INDICATE A MALFUNCTIONING SOFTENER OR CONDENSATE CONTAMINATED WITH POTABLE WATER CONTAINING HARDNESS.

PHOSPHATE CHEMICAL USED	=	SODIUM HEXAMETAPHOSPHATE
ACTUAL PHOSPHATE DOSAGE (POUNDS/DAY) =		3.54
CALCULATED PHOSPHATE DOSAGE (LBS/DAY) =		2.35

ALTERNATE SLUDGE CONDITIONER USED	=	CPI

 POUNDS OF SODIUM HYDROXIDE (NAOH) REQUIRED PER 100 POUNDS OF PHOSPHATE  
 CHEMICAL = 78.4000

RESIDUAL  $\text{PO}_4$  DESIRED IN BOILER (PPM  $\text{PO}_4$ ) = 48.30  
 POUNDS OF PHOSPHATE CHEMICAL/DAY FOR RESIDUAL = 0.93  
 POUNDS OF PHOSPHATE CHEMICAL/DAY FOR CA HARDNESS = 1.81  
 TOTAL POUNDS-PHOSPHATE CHEMICAL/DAY-ADVANCED CALC = 2.74  
 ACTUAL DOSAGE OF PHOSPHATE CHEMICAL (LB/DAY) = 3.54

\*\*\*\*\* DETERMINE CAUSTIC SODA DOSAGE PER DAY \*\*\*\*\*

PURITY (%) OF CAUSTIC SODA USED = 98.00  
 NAOH POUNDS/DAY FOR  $\text{PO}_4$  HYDROLYSIS-ADVANCED CALC = 2.19  
 NAOH POUNDS/DAY FOR CALCIUM HYDROXYAPATITE = 0.23

CALCULATED MAGNESIUM HARDNESS IN FEEDWATER = 0.79  
 CALCULATED SILICA IN FEEDWATER = 5.54  
 SILICA IN FEEDWATER BY TEST = 6.00  
 SILICA NEEDED FOR MAGNESIUM REACTIONS = 1.47

NAOH POUNDS/DAY FOR MAGNESIUM HYDROXIDE	=	0.00
NAOH POUNDS/DAY FOR SERPENTINE (MG+SILICA)	=	0.07
TOTAL NAOH POUNDS/DAY FOR MAGNESIUM REACTIONS	=	0.07

SUFFICIENT SILICA FOR MAGNESIUM REACTION TO FORM SERPENTINE.

HYDROXYL RESIDUAL DESIRED (PPM CAC03)	=	286.20
HYDROXYL RESIDUAL BY TEST	=	286.20

BREAKDOWN OF NATURALLY OCCURRING ALKALINITY GIVES

TOTAL ESTIMATED HYDROXYL ALKALINITY IN BOILER	=	928.71
---	---	--------

ESTIMATED HYDROXYL ALKALINITY IN BOILER IS HEAVILY DEPENDENT ON PERCENT CARBONATE ALKALINITY SELECTED, USE OF NEUTRALIZING AMINES, AND REACTIONS NOT TAKEN INTO ACCOUNT. ACTUAL VALUES MEASURED MAY BE AS LITTLE AS 20 PERCENT OF THE ABOVE ESTIMATE.

THERE IS NO HYDROXYL DEFICIENCY IN ATTAINING THE DESIRED RESIDUAL!

EXCESS HYDROXYL ALKALINITY TO MEET RESIDUAL NEEDS.

IF OH ALKALINITY IN BOILER EXCEEDS 500 PPM (AS CAC03) THEN INVESTIGATE USE OF DEALKALIZATION, ACIDIC TREATMENT CHEMICALS, OR REDUCE CAUSTIC FOR HYDROLYSIS.

ESTIMATED REDUCTION IN NAOH (POUNDS/DAY) DUE TO NATURALLY OCCURRING ALKALINITY

NAOH POUNDS/DAY FOR RESIDUAL	=	9.14
	=	0.00

\* NO CAUSTIC SODA REQUIRED!

CAN REDUCE EQUIVALENT CAUSTIC SODA POUNDS/DAY BY	6.64
--	------

\*\*\*\*\* DETERMINE LIGNOSULFONATE DOSAGE PER DAY \*\*\*\*\*

RESIDUAL PPM LIGNOSULFONATE DESIRED	=	85.00
PURITY (%) OF LIGNOSULFONATE CHEMICAL	=	100.00
LIGNOSULFONATE DOSAGE FOR RESIDUAL	=	1.48
LIGNOSULFONATE DOSAGE FOR FDWTR 20 % M ALKALINITY	=	0.19
LIGNOSULFONATE DOSAGE REQUIRED (POUNDS/DAY)	=	1.48
ALTERNATE SLUDGE CONDITIONER USED	=	CPI
ACTUAL DOSAGE OF SLUDGE CONDITIONER (LB/DAY)	=	8.00

\*\*\*\*\* DETERMINE SULFITE DOSAGE PER DAY \*\*\*\*\*

THE DEAERATING HEATER IS NOT BOILING PROPERLY! CHECK CALIBRATION OF THE GAUGES AND TEST THE OXYGEN CONTENT OF THE FEEDWATER.  
DESIGN LIMIT PPM O2 FROM DEAERATOR NOT ACHIEVED = 0.4850

RESIDUAL SULFITE (PPM S03) DESIRED	=	49.50
PURITY (%) OF SULFITE CHEMICAL	=	90.00
SODIUM SULFITE NEEDED FOR RESIDUAL	=	1.50
SODIUM SULFITE NEEDED FOR OXYGEN LEAKAGE	=	1.54
SODIUM SULFITE REQUIRED (POUNDS/DAY)	=	3.05
ACTUAL DOSAGE OF SODIUM SULFITE (LB/DAY)	=	3.05

\*\*\*\*\* DETERMINE NEUTRALIZING AMINE DOSAGE \*\*\*\*\*

\*\*\*\*\* FOR A 50/50 MIXTURE OF \*\*\*\*\*  
 \*\*\*\*\* CYCLOHEXYLAMINE AND MORPHOLINE \*\*\*\*\*

P ALKALINITY IN FEEDWATER BY TEST	=	0.00
CALCULATED M ALKALINITY IN FEEDWATER	=	55.63
M ALKALINITY IN FEEDWATER BY TEST	=	60.00

PER CENT OF CARBONATE ALKALINITY BREAKDOWN	=	80.00
CALCULATED FEEDWATER BICARBONATE ALKALINITY	=	55.63
CALCULATED FEEDWATER CARBONATE ALKALINITY	=	0.00
EQUIV CARBON DIOXIDE (PPM CO2) IN FEEDWATER	=	44.06

PURITY (%) OF CYCLOHEXYLAMINE USED	=	60.00
PURITY (%) OF MORPHOLINE USED	=	40.00
CYCLOHEXYLAMINE DISTRIBUTION RATIO	=	9.00
MORPHOLINE DISTRIBUTION RATIO	=	0.85
CYCLOHEXYLAMINE DOSAGE (LB/DAY)	=	6.10
MORPHOLINE DOSAGE (LB/DAY)	=	8.79

NOTE THE MIXTURE RATIOS AND MAXIMUM DOSAGES ALLOWED FOR NEUTRALIZING AMINES  
 PER AFP 91-41.

DO NOT USE AMINES IF STEAM COMES INTO DIRECT CONTACT WITH FOOD. IMMEDIATELY  
 HAVE SERVICES PROGRAM EQUIPMENT REPLACEMENT AS THIS IS AGAINST STATED POLICY.

ACTUAL DOSAGE OF CYCLOHEXYLAMINE	(LB/DAY)=	5.71
ACTUAL DOSAGE OF MORPHOLINE	(LB/DAY)=	0.00

\*\*\*\*\* BOILER QUALITY OF INTEREST \*\*\*\*\*  
 \*\*\*\*\* FROM WATER TREATMENT LOG (AF FORM 1459) \*\*\*\*\*

HYDROXYL ALKALINITY	(PPM CaCO3)	286.20
TOTAL DISSOLVED SOLIDS	(PPM)	1,524.70
PHOSPHATE	(PPM PO4)	48.30
SULFITE	(PPM SO3)	49.50
LIGNOSULFONATE	(PPM TANNIC ACID)	0.00
PH		11.29

TEMPER COMMENTS BELOW IF ALTERNATE CHEMICALS ARE USED VICE AFP 91-41 STOCKS.

TDS OPERATING LEVEL IS LOW - WASTE OF ENERGY AND CHEMICALS!

WARNING-CALCULATIONS PREDICT EXCESSIVE SUSPENDED SOLIDS IN BOILER.  
 INVESTIGATE

HARD MAKEUP WITH NO PHOSPHATE, SOFTENING AND PHOSPHATE, AND ELIMINATION OF  
 CONDENSATE RETURN HARDNESS CONTAMINATION!

TDS ABOVE EXPECTED RANGE - MAY CAUSE DAMAGING BAKED-ON SLUDGE OR SILICA SCALE!

HYDROXYL ALKALINITY OR BOILER PH IS LOW - EXPECT CORROSION AND BAD REACTIONS!

LIGNOSULFONATE OPERATING LEVEL IS LOW - MAY RESULT IN BAKED-ON SLUDGE!

WARNING-CALCULATED BOILER M ALKALINITY EXCEEDS 20% OF BOILER TDS. THIS CAUSES DETRIMENTAL FOAMING. SPLIT-STREAM SOFTEN, DEALKALIZE, OR USE SODIUM BISULFITE TO REDUCE ALKALINITY.

\*\*\* SUMMARY OF ACTUAL AND CALCULATED CHEMICAL DOSAGES \*\*\*

ANALYSIS NOTE - IF PURPOSE IS TO MODEL ACTUAL SYSTEM OPERATION, THEN DATA RECORD SHOULD REFLECT THE OPERATIONAL LIMITS BEING USED FOR EACH CHEMICAL OR TEST AND THE MAKEUP SHOULD BE CONSTRAINED TO THE ACTUAL METERED MAKEUP VALUE. THIS SHOULD RESULT IN BLOWDOWN EQUIVALENCE BETWEEN ACTUAL SYSTEM AND CALCULATED RESULTS THEN COMPARISON OF ACTUAL AND CALCULATED DOSAGES IS OF VALUE. FOR EXAMPLE - ACTUAL SULFITE DOSAGE GREATER THAN CALCULATED COULD INDICATE MORE OXYGEN IN THE FEEDWATER THAN ESTIMATED, AN OUT OF CALIBRATION PRESSURE OR TEMPERATURE GAUGE ON THE DEAERATING HEATER, OR A DEFECTIVE DEAERATING HEATER SIMILARLY, A HIGH PHOSPHATE DOSAGE CAN INDICATE A MALFUNCTIONING SOFTENER OR CONDENSATE CONTAMINATED WITH POTABLE WATER CONTAINING HARDNESS.

PHOSPHATE CHEMICAL USED	=	SODIUM HEXAMETAPHOSPHATE
ACTUAL PHOSPHATE DOSAGE (POUNDS/DAY) =		3.54
CALCULATED PHOSPHATE DOSAGE (LBS/DAY) =		2.74

ALTERNATE SLUDGE CONDITIONER USED	=	CPI
ACTUAL SLUDGE CONDITIONER (LBS/DAY) =		8.00
CALCULATED LIGNOSULFONATE (LBS/DAY) =		1.48

ACTUAL SODIUM SULFITE (POUNDS/DAY) =		3.05
CALCULATED SODIUM SULFITE (LBS/DAY) =		3.05

ACTUAL CYCLOHEXYLAMINE (POUNDS/DAY) =		5.71
ACTUAL MORPHOLINE (POUNDS/DAY) =		0.00
CALCULATED CYCLOHEXYLAMINE (LBS/DAY) =		6.10
CALCULATED MORPHOLINE (LBS/DAY) =		8.79

RUN THE BASIC ANALYSIS CALCULATIONS TO RECEIVE INTERPRETATION OF THE SYSTEM OPERATION DATA AND AN INITIAL CALCULATION OF CHEMICAL DOSAGES PER AFP 91 41. NOTE THAT AFP 91-41 ASSUMES NO STEAM OR CONDENSATE LOSSES AND ESTIMATES DAILY DOSAGES AT A HIGH LEVEL DUE TO USE OF A CYCLE OF CONCENTRATION THAT DOES NOT TAKE INTO ACCOUNT THE CHEMICALS ADDED.
